Question Why do metals conduct electricity while nonmetals usually don't? Metals have free electrons that move easily, allowing them to conduct electricity. Nonmetals lack these free electrons, so they generally don't conduct electricity well. What happens when you mix metals and acids in experiments? When metals react with acids, they often produce bubbles of hydrogen gas and form a new substance called a salt. For example, zinc reacting with hydrochloric acid produces zinc chloride and hydrogen gas. Why do some metals like iron rust when exposed to water and air? Iron reacts with water and oxygen, forming iron oxide, which is rust. This process is called oxidation and causes the metal to weaken and change color. How can you test if a material is a metal or nonmetal? You can test if a material is a metal by checking if it conducts electricity, is shiny, and can be shaped easily. Nonmetals usually do not conduct electricity and are often brittle or dull. What is a safe way to see how metals react with acids at home? With adult supervision, you can use a small piece of zinc or magnesium and a safe, diluted acid like vinegar. Observe the bubbles and reactions carefully, but always be cautious and wear safety goggles. Can nonmetals be used to make conductors like metals? Most nonmetals are not good conductors, but some, like graphite (a form of carbon), can conduct electricity and are used in pencils and batteries.
